

NORTH METRO DERMATOLOGY

Cryosurgery (liquid nitrogen) Instructions

Cryosurgery (also known as “cold surgery”) is a common dermatological treatment used to destroy unhealthy tissue. Several treatments may be needed which are typically repeated every 4-6 weeks.

Common side effects:

- A pink or red color change of the skin
- A sore/crust
- A water blister
- A blood blister

It is important to care for treated site(s) to avoid infection and minimize scarring. Follow these instructions until skin is well healed:

1. Gently cleanse wound twice daily with water and gentle cleanser (we recommend unscented Dove, Vanicream, Cetaphil or Skin Wise Organics Gentle Cream Cleanser) or spray wound twice daily with EltaMD Dermal Wound Cleanser.
2. To prevent scabbing, keep the treatment area moist with Bacitracin (available at most pharmacies) or a neutral ointment (Vaseline, Aquaphor, or Skin Wise Organics Soothing Barrier Ointment).
3. If located where it may become dirty or where clothing or other friction may manipulate it, then apply a bandage or other non-stick dressing.
4. If you get a blister, allow the blister to “pop” and collapse on its own. The “roof” of the blister should not be removed since it serves purposeful protection.
5. Tylenol may be used to relieve minor discomfort (one or two 325 mg tablets every 4-6 hours as needed).

Call the office or seek medical attention if:

1. The area around the wound becomes painful or hot to the touch.
2. You see pus in the wound or red streaks extending from the wound.
3. You develop a fever.

Please contact our office if you have any questions or concerns.
